

### Test Automation feasibility Analysis for Beginners:

Appropriate tool selection. Depends on the nature of the application, sometimes existing in house tools can help. This information we can very well share it to client with relevant details and, if they agree, we can go-ahead and proceed. This can help to save budget and effort.

Also, we can suggest any migration is possible from existing licensed tools to free tools which are available in Market , which can support the application, if not we can suggest , to migrate the existing scripts to freeware by analysing the existing script algorithms by automation experts or engineers, initially effort may require bit more, reason to analyse the script algorithms and migrated it to chosen freeware, going further we can save much more budget, mostly this will help for long run applications.

Sometimes, we need to go with client suggestion like, if they are very restricted on their automation suite, they are already having few scripts,. Which are developed for ex: in QTP or any other client in-house tools, we need to continue with the same existing scripts with exiting automation framework.

Appropriate tool selection, again nature of the application, and whether the selected tool supports the type of application, with respect to technology in which the application built and that technology our automation tool supports etc..

### Evaluate the suitable framework, based on the type of application.

- If the application changes are within the web controls, we no need interact with any external data providers, we can go with keyword.
- If we need to co-ordinate with external data source plus changes within the web controls go for keyword +Data driven, i.e called as Hybrid frame work
- Sometimes, we may need to customize the existing framework according our needs or sometimes we need build our own framework, based on the work flows and data flows with in our application.
- Again it depends on the available modules or work flows or budget, no.of resources and further maintenance
- Finally Build the Proof of Concept- Here needs to develop with an end to end scenario to evaluate, to know, if the sleeted tool can support the Automation of the Application.

Also, below is the basic flow of architecture diagram with one of the popular tool in Market.

### Automation Flow Diagram
